

Multithreaded Flight Information Client-Server System

Overview

This project is a multithreaded client-server application that retrieves and displays real-time flight information using the Aviationstack API.

Problem

Travelers and airport users often require timely access to flight arrival and delay information through a centralized service.

Solution

The system retrieves flight information from an external API and delivers results through secure client-server communication.

Key Features

- Real-time flight information retrieval
- Arrived flight tracking
- Delayed flight monitoring
- Flight details lookup
- Multi-client support
- SSL/TLS-secured communication

Technologies Used

- Python
- Socket Programming
- Threading
- SSL/TLS
- JSON
- Aviationstack API

My Contributions

- Developed the client-server architecture
- Implemented multithreading for concurrent users
- Integrated the Aviationstack API
- Configured SSL/TLS secure communication
- Processed and displayed flight information

Outcome

Created a secure network application capable of serving multiple users simultaneously while providing real-time flight data.
